Meiosis and Fertilization – Understanding How Genes Are Inherited

Introduction

1a. What is a gene?

1b. What processes ensure that each cell in your body has a complete set of chromosomes with all the genes?

2. Summarize what you already know about how a child inherits one copy of each gene from each parent.

To understand how genes are inherited, you will need to learn what happens to the gene-carrying chromosomes during:

- Meiosis – a special type of cell division that produces eggs and sperm
- Fertilization – a sperm unites with an egg to produce a zygote (a fertilized egg)

3. To summarize how a child inherits one copy of each gene from each parent, fill in each blank in this flowchart.

4. The zygote has all the chromosomes with all the genes that were in the egg and sperm. What problem would occur if eggs and sperm were produced by mitosis?

---

1 by Drs. Ingrid Waldron, Jennifer Doherty, R. Scott Poethig, and Lori Spindler, Department of Biology, University of Pennsylvania, © 2021; Word files for this Student Handout and Teacher Preparation Notes with background information and instructional suggestions are available at https://serendipstudio.org/sci_edu/waldron/#meiosis.
To understand the biological solution to the problem that would occur if eggs and sperm were made by mitosis, we need to think about pairs of homologous chromosomes.

5. What is a pair of homologous chromosomes?

- A **diploid** cell has pairs of homologous chromosomes. Almost all the cells in your body are diploid.
- A **haploid** cell has only one chromosome from each pair of homologous chromosomes.

6a. Circle each pair of homologous chromosomes in this figure.

6b. How many copies of each gene are in a diploid cell?

6c. How many copies of each gene are in a haploid cell?

As a result of meiosis, each egg or sperm receives one chromosome from each pair of homologous chromosomes in the parent.

7a. Label the cells in this figure that are haploid.

7b. Circle a pair of homologous chromosomes in the zygote.

7c. Match each item in the top list with the best match from the bottom list.

Diploid cell → diploid cells ___
Diploid cell → haploid cells ___
Haploid cells → diploid cell ___
a. Fertilization  b. Meiosis  c. Mitosis

8. Use the information you have learned thus far to explain how each cell in a child gets one copy of each gene from his/her mother and another copy of each gene from his/her father. A complete answer will include the following terms:

meiosis, haploid, egg, sperm, pair of homologous chromosomes, gene, fertilizes or fertilization, diploid, zygote, DNA replication, mitosis
How Meiosis Makes Genetically Diverse Haploid Gametes

Eggs and sperm are called **gametes**. The figure below shows how a diploid cell divides into haploid gametes. First, the DNA in a diploid cell is replicated and then two cell divisions produce haploid gametes. In the figure, the initial cell has one pair of homologous chromosomes, with alleles labeled for only one of the many genes on that chromosome.

9. Each paragraph below describes one step in meiosis. Draw an arrow from each paragraph to the matching part of the figure.

At the beginning of **meiosis I**, the pair of homologous chromosomes are lined up next to each other and the two copies of the DNA in each chromosome are condensed into sister chromatids.

During **meiosis I**, the homologous chromosomes are separated into two daughter cells. These daughter cells are haploid since they have one chromosome from each pair of homologous chromosomes.

During **meiosis II**, the sister chromatids of each chromosome are separated. Meiosis II produces four haploid daughter cells that become gametes.

10a. The A and a alleles are only labeled on some of the chromosomes or chromatids. Use your understanding of DNA replication and meiosis to label the A or a alleles on the other chromosomes and chromatids.

10b. Use * to mark two gametes that have different genes.

11. To produce haploid gametes, DNA is replicated __ time(s), followed by __ cell division(s).

12. To describe the characteristics of meiosis I, meiosis II, and mitosis, put a check for each characteristic that applies.

Next, you will model meiosis using a pair of model chromosomes with the alleles shown here.

A. Use your pair of model chromosomes to model each step of meiosis. Use your arms as spindle fibers to move the chromosomes, and use erasable marker, chalk or string to represent the cell membranes at each stage.

13a. Show the results of your modeling in this flowchart. Draw and label the chromosomes in each cell that is produced by meiosis I and by meiosis II.

13b. Which two combinations of alleles do you observe in the gametes?

_____ah_____ _____

When a pair of homologous chromosomes is lined up next to each other at the beginning of meiosis I, the two homologous chromosomes can exchange parts of a chromatid. This is called crossing over. This figure shows crossing over for a pair of homologous chromosomes that begins with one chromosome that has the A and H alleles and another chromosome that has the a and h alleles.

14. Label the alleles for these genes on each chromatid of the chromosomes in the bottom row.

Meiosis will separate the pair of homologous chromosomes and then the sister chromatids. This will produce gametes with four different combinations of the alleles for the two labeled genes.

15. The combinations of alleles in the different gametes will be:

_____ _____ _____ _____
Next, you will model meiosis using the two pairs of homologous chromosomes shown in the chart below. Notice that the two pairs of homologous chromosomes can line up in two different ways at the beginning of meiosis I – the chromosome with the i allele can be on the same side as the chromosome with the ah alleles or the chromosome with the AH alleles. This is called independent assortment, since each pair of homologous chromosomes lines up independently of how the other pair of homologous chromosomes lines up.

B. Use your two pairs of homologous chromosomes to model meiosis I and meiosis II for each of the possible ways of lining up the model chromosomes at the beginning of meiosis I.

16. Complete this chart. Draw the missing chromosomes and label the alleles on each chromatid and chromosome.

<table>
<thead>
<tr>
<th>Chromosomes at the beginning of Meiosis I</th>
<th>Chromosomes at the end of Meiosis I</th>
<th>or</th>
</tr>
</thead>
<tbody>
<tr>

<td>______ or _______</td>
</tr>
<tr>
<td>![Diagram of chromosomes]</td>
<td>______ or _______</td>
</tr>
</tbody>
</table>

Crossing over could produce gametes with four additional combinations of alleles (ahI, aHi, AhI and Ahi) for a total of eight combinations of alleles for these three genes.

17. The total amount of genetic diversity in the gametes produced by one person is huge. Each human body cell has roughly 20,000 genes on 23 pairs of homologous chromosomes. Independent assortment of 23 pairs of homologous can produce more than 8 million different combinations of chromosomes! The number of different combinations of alleles in the gametes is even greater due to ____________ _______ at the beginning of meiosis I.
Genes are inherited via meiosis and fertilization.

To learn how meiosis and fertilization determine the genetic makeup of a child, you will analyze inheritance for two parents who both have the Aa genotype. This flowchart shows how these parents could have a child with the Aa genotype.

18a. Fill in the blanks in this flowchart to show when meiosis and fertilization occurred.

18b. Label the alleles in the child’s cells. Explain how you know what these alleles are.

18c. Do you think that this is the only possible outcome of meiosis and fertilization for these two Aa parents? Explain why or why not.

C. To investigate the possible outcomes of meiosis and fertilization for these Aa parents, you will model meiosis and fertilization with chromosomes that look like these.

D. To prepare the mother’s model chromosomes, use a pair of ah and AH model chromosomes. Tape blank strips of paper to cover the h and H alleles.

E. To prepare the father’s model chromosomes, use a different color pair of the i and I model chromosomes. First, cover the i and I alleles with blank strips of paper. Then, use strips with the a allele or the A allele to finish preparing the father’s model chromosomes.
F. This chart will guide you as you model meiosis and fertilization. Outline the rectangles of this chart on your lab table, using chalk, dry erase marker or tape. Each white rectangle should be big enough for a model chromosome, and each gray rectangle should be big enough for two.

G. Use one pair of model homologous chromosomes to demonstrate how meiosis produces eggs. Put a model chromosome for each type of egg in the top boxes in your chart on your lab table.

H. Use the other color pair of model homologous chromosomes to demonstrate how meiosis produces sperm. Put a model chromosome for each type of sperm in the boxes on the left in your chart on your lab table.

19. Write the allele for each type of egg and sperm in the appropriate white boxes in the above chart.

I. Model fertilization by moving the chromosome from one of the eggs and the chromosome from one of the sperm to produce a zygote which will have one chromosome from the egg and one from the sperm.

J. Repeat, using each type of sperm to fertilize each type of egg.

20. Write the genetic makeup of each type of zygote in the appropriate gray box in the chart.

21a. Use the information in the table below to determine the phenotypic characteristic (albinism or normal skin and hair color) of the mother, the father, and the child who would develop from each zygote. Write these phenotypes in the above chart.

<table>
<thead>
<tr>
<th>Genotype</th>
<th>Phenotype (characteristics)</th>
</tr>
</thead>
<tbody>
<tr>
<td>AA or Aa</td>
<td>Normal skin and hair color</td>
</tr>
<tr>
<td>aa</td>
<td>Albinism (very pale skin and hair color)</td>
</tr>
</tbody>
</table>

21b. In the chart near the top of the page, circle the genotypes of each zygote that would develop into a person with the same phenotypic characteristic as the parents. Use an * to mark the zygote that would develop into a person who would have a different phenotypic characteristic that neither parent has.

22a. Explain why children often have the same phenotypic characteristics as their parents.

22b. Explain how a child can have albinism when neither parent has albinism.
Each person has thousands of genes in 23 pairs of homologous chromosomes, so crossing over and independent assortment can produce millions of different combinations of alleles in his/her gametes. If each different type of egg from one mother could be fertilized by each different type of sperm from one father, this would produce zygotes with trillions of different combinations of alleles.

23. Explain why no two siblings inherit exactly the same combination of alleles from their parents (except for identical twins who both developed from the same zygote). A complete answer will include the following terms:
   - homologous chromosomes
   - genes
   - alleles
   - meiosis
   - crossing over
   - independent assortment
   - gametes
   - egg
   - sperm
   - fertilization
   - zygote

Sexual vs. Asexual Reproduction

Thus far, we have been discussing sexual reproduction in humans. Asexual reproduction involves only mitosis, without meiosis and fertilization. Many types of plants and some types of animals have asexual reproduction.

This figure shows one type of asexual reproduction. Repeated mitosis produces the cells that form a bud. Then, the bud breaks off to form a daughter hydra.

A hydra is an animal that lives in the water and uses its tentacles to catch food.

24. Are there any genetic differences between the mother hydra and the daughter hydra? Explain your reasoning.

25a. What would be the advantage of asexual reproduction for an organism that lives in a stable environment that does not change?

25b. What would be the advantage of sexual reproduction for an organism that grows in a variable environment that often changes?
